Resume : Hybrid structures are needed to fully exploit the great  
advantages of Si photonics and different approaches have been  
addressed where Si devices are bonded to different materials and  
nanostructures. Here we experimentally study the use of semiconductor  
carbon nanotubes for emission in the 1300 nm wavelength range to  
functionalize Si photonic structures in view of optoelectronic applications.  
The Si microrings are fully characterized by near field forward resonant  
scattering with 100 nm resolution. We show that both TE and TM modes  
can be addressed on the top of the microrings in a vectorial imaging of  
the in-plane polarization components. We coupled the Si  
microresonators with selected carbon nanotubes for high  
photoluminescence emission. Coupling of the nanotubes with the  
evanescent tails in air of the electric field localized in the photonic modes  
of the microresonators is demonstrated by sharp resonances  
overimposed to the nanotube emission bands. By mapping the Si and  
the nanotubes emission we demonstrate that strong enhancement of the  
nanotubes photoluminescence can be achieved both in the photonic  
modes of microdisks and slot microrings, whenever the spatial overlap  
between nanoemitters and photonic modes is fulfilled.
