HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Alkali-metal-catalyzed synthesis of isoureas from alcohols and carbodiimides¹

Current synthetic methods for the formation of isoureas rely on the addition of the alcohol (R'OH) to the corresponding carbodiimide (RN=C=NR). State-of-the-art catalysts rely on transition metal and actinide complexes. Copper (CuCl, CuCl₂, Cu₂O) and zinc (ZnCl₂) salts are reported to act as Lewis acids², able to enhance the electrophilicity of the carbodiimide reagent. Recently, in 2016, Eisen described new actinide complexes³ (U[N(SiMe₃)₂]₃ and [(Me₃Si)₂N]₂An[κ²(N,C)-CH₂Si(CH₃)₂N(SiMe₃)] (An = Th or U)) able to catalyze the formation of isoureas under mild conditions.

Capitalizing on our knowledge on the chemical reactivity of guanidine bases⁴ and alkali metal like Lewis acid, we have recently designed the first alkali metal catalysts able to facilitate the addition of alcohols to carbodiimides.¹ The role and influence of the alkali metal has been investigated by controlling the Lewis acidity of the alkali metal with exogenous ligands. Experimental studies, combined with DFT calculations, offer a new vision on the active role of alkali metal cations in catalysis.
