HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Background of the study: Vitrification of the nuclear high level wastes

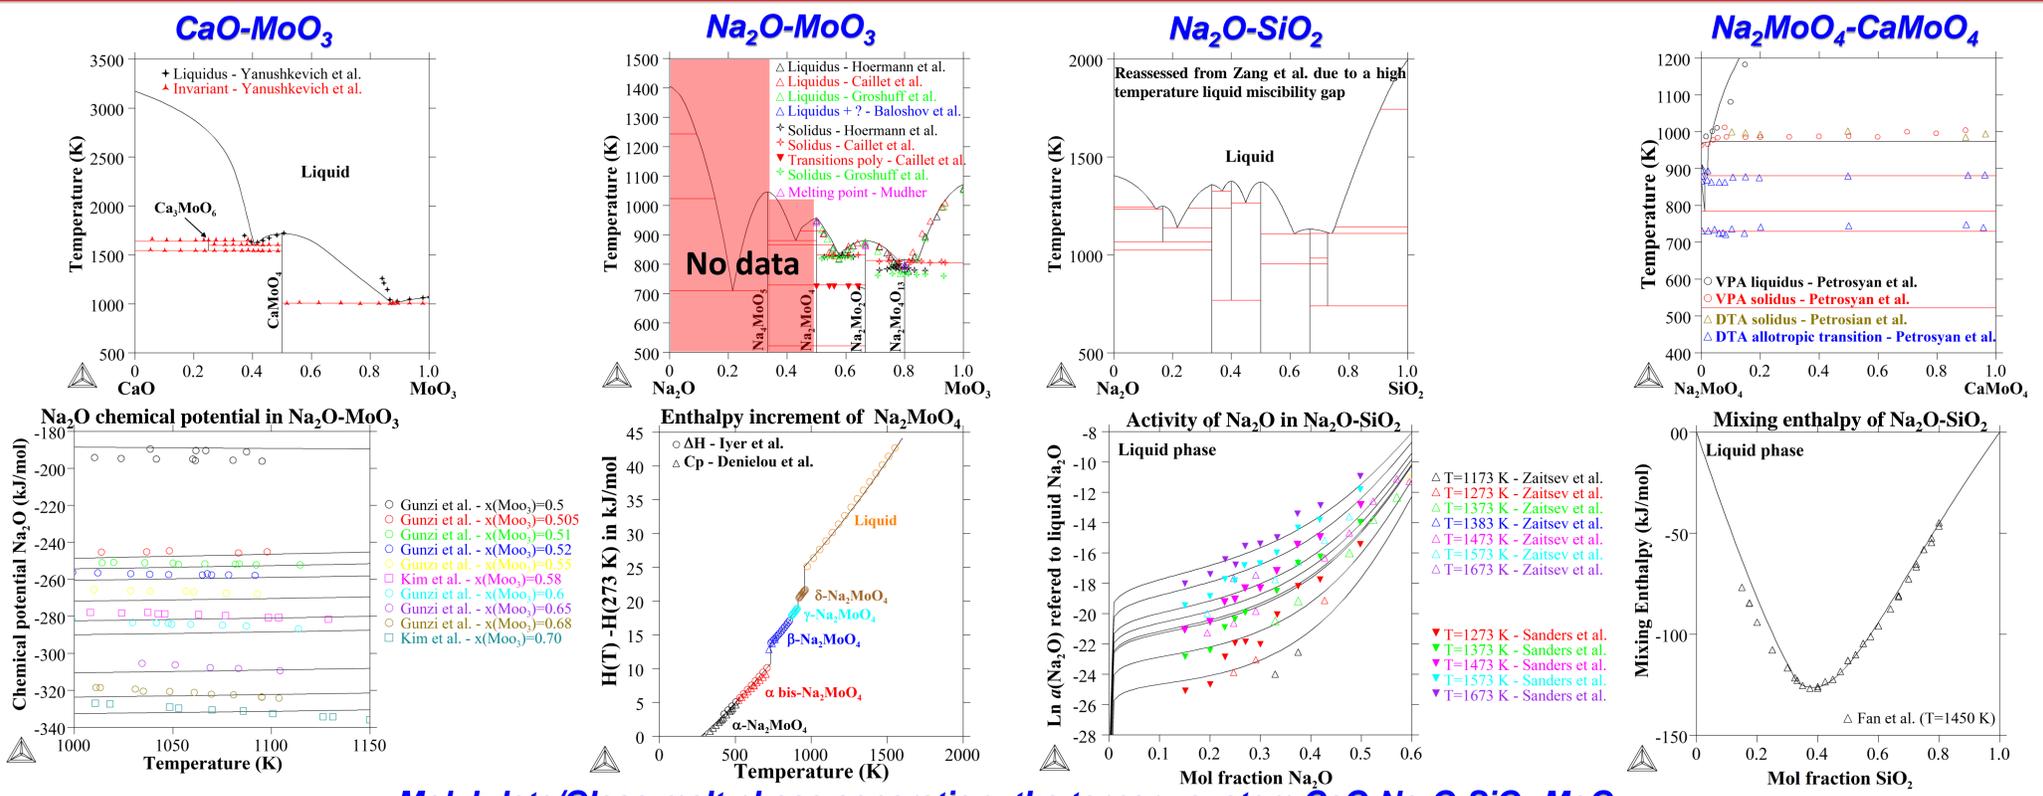

Fission products and actinides arising from the spent UOX fuel reprocessing are vitrified in borosilicate glasses. Among the fission products, platinum-group metals (Pd-Rh-Ru) exhibit very low solubility and partly precipitate as metal or oxide phases in the melt, molybdenum interacts with the glass frit to form molybdate phases known to precipitate as a complex phase called “yellow phase”. These platinoid and molybdate phases may induce modifications of the physico-chemistry of the glass melt and alter the final glass confinement properties. To understand the relative stability of these phases depending on both temperature and oxygen potential of the melt, a thermodynamic database is being developed using the Calphad method.

To consider the formation of molybdates, the CaO-MoO₃ and the Na₂O-MoO₃ pseudo-binary systems are assessed. The modeling of the Na₂O-SiO₂, MoO₃-SiO₂ and of the ternary SiO₂-Na₂O-MoO₃ system was carried out based on the literature and on new experiments in order to consider a simplified glass melt. Furthermore, the developed database includes the metallic and oxide complex platinoid system and some of the interactions with selenium and tellurium: Pd-Rh-Ru-Se-Te-(O).

Using this tool, the thermodynamic behavior of the platinoid and molybdate phases is calculated as a function of temperature and composition. This study throws new light on the interactions between poorly soluble fission products and the glass melt during the vitrification process of high level nuclear wastes.

Results of the modeling

Conclusions and prospects

The modeling of CaO-MoO₃, Na₂O-MoO₃, Na₂MoO₄-CaMoO₄ and of SiO₂-Na₂O-MoO₃ systems has been carried out. This study makes it possible to predict the formation of the molybdate phases in the simplified glass melt. The next step will focus on the introduction of B₂O₃ in the database to get closer to the real industrial glass composition.

The Pd-Se and Pd-Te systems have been modeled. An assessment of the Pd-Se-Te system will be available soon. In parallel, the Rh-Ru-O database enables to calculate the speciation of the platinoids in the glass as a function of oxygen potential and temperature.

This work will help to predict the high temperature interactions between some poorly soluble fission products (Mo, Pd, Rh, Ru) and the glass melt during the vitrification process, of nuclear wastes
