HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Effect of cumulated dose on gas emission and oxygen consumption from polyethylene irradiated under oxidative atmosphere using Swift Heavy Ions

Context

- Intermediate Level Long Lived Waste (IL-LLW) : various organic materials, including polymers, in presence of radionuclides
 - Production of potentially explosive (hydrogen, methane...) or corrosive (hydrogen chloride, fluoride...) gases
- In the French nuclear safety context: development of a 500-meter deep disposal concept for IL-LLW
 - Quantification of the gaseous compounds release, as a function of the polymer
 - Doses higher than tens or one hundred of MGy => chemical composition of organic materials highly modified

Aim

- Study of the influence of the irradiation dose on gas emission and oxygen consumption
 - Doses consistent with IL-LLW [1]

Polymers used in the French electronuclear industry

■ Polyurethane
 ■ Chlorinated polymers
 ■ Polyolefins
 ■ Polyamides
 ■ Cellulose
 ■ Fluorinated polymers
 ■ Ion-exchange resin
 ■ Other polymers

Ionizing radiations encountered in IL-LLW

Projected deep underground geological repository

IL-LLW tank

Material

- HDPE (High Density Polyethylene)
- Thin films prepared by high pressure molding
 - To ensure homogeneous oxidation profile in the sample thickness

Irradiation conditions : a 2 step-irradiation procedure [2]

- Pre-aging: irradiation at high and various doses, under oxygen, without gas analysis
- Gas emission and oxygen consumption quantification: irradiation at low dose in closed container, along with gas analysis
- Storage conditions: pre-aged polymers stored under inert atmosphere and in the dark
- Result analysis

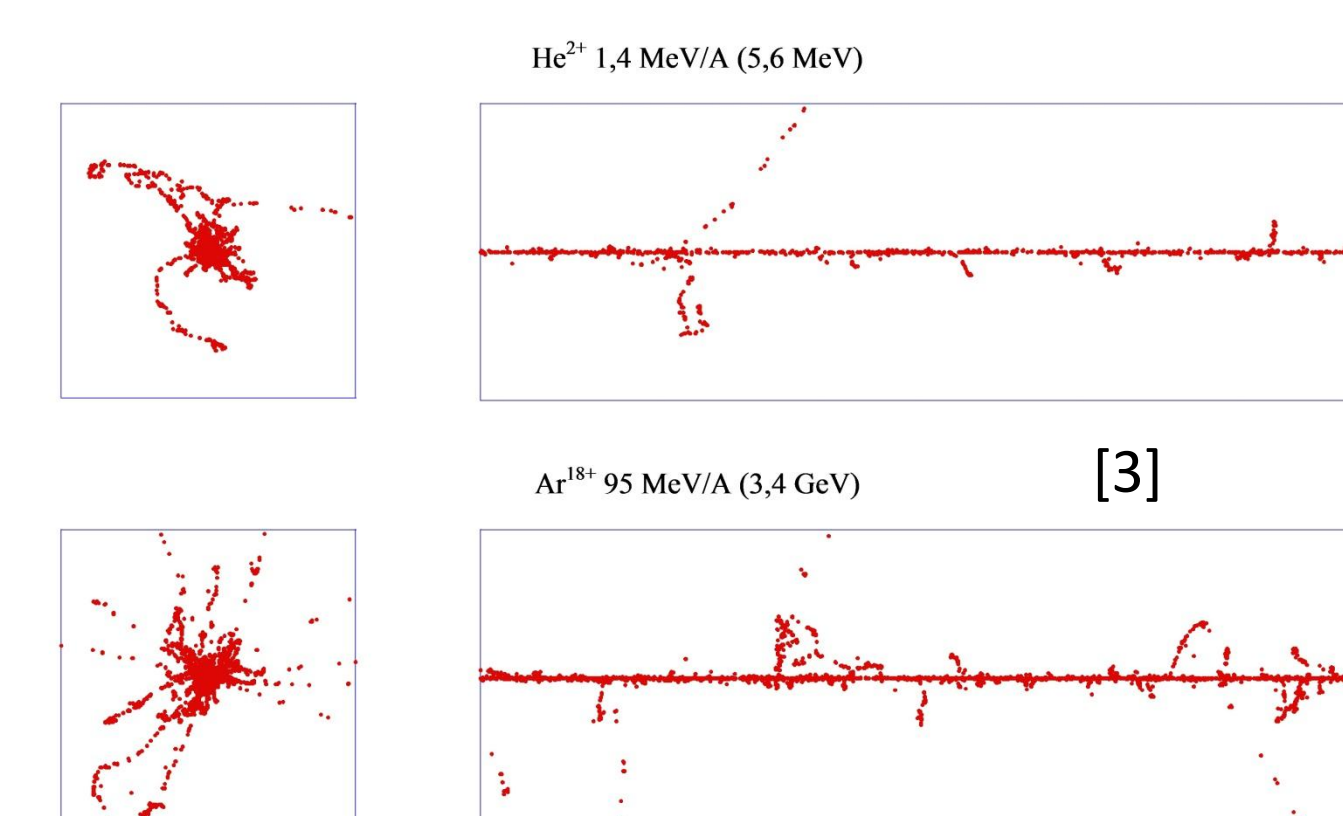

Ion beams to simulate α irradiations

- Why SHI (Swift Heavy Ions) instead of α ?
 - LET (Linear Energy Transfer) equivalent to radionuclides-emitted α
 - Higher penetration range

- Pre-aging: ¹³C (10 MeV/A) beams
 - Medium Energy beam line of GANIL (3.6·10⁸ ions.cm⁻².s⁻¹ up to 1.2·10¹³ ions.cm⁻²)
- Gas emission and oxygen consumption quantification: ³⁶Ar (95 MeV/A) beam
 - High Energy beam line of GANIL (3.6·10⁸ ions.cm⁻².s⁻¹ up to 2.6·10¹² ions.cm⁻²)
 - => Necessity to go through glass walls of the closed containers
 - => Necessity to ensure constant LET through samples thickness

- In HDPE :
 - Equivalent excitation densities along the ion track with both ion beams
 - But: difference in radial repartition of dose
- No LET effect on the formation of ketone defects (in the LET range explored) [4]

Hydrogen emission

- H₂ instantaneous emission rate ↘ when dose ↗
 - Previously observed by Seguchi [5]
 - => Under vacuum and gamma rays up to 2 MGy
 - => Assigned to energy transfers towards radiation-induced C=C double bonds
 - In this work, first evidence of radiation protection
 - => Under oxidative atmosphere and ion beam up to doses as high as 10 MGy
 - => Assigned to energy transfers towards oxidized defects (for ketone defects, observed by Slivinskas & Guillet under gamma-rays [6])

Oxygen consumption and carbon oxides emission

- When dose ↗: O₂ consumption and CO and CO₂ emission instantaneous rates ↗ and then →
- Competing reactions
 - ↘ in radiation-induced radical formation on the non-modified polymer
 - => Evidenced by the decrease of hydrogen formation with dose
 - ↗ of oxidized defects degradation
 - => Direct action of irradiation
 - => By energy transfer on these oxidized defects (like hydroperoxides) acting as energy sinks
- At high doses: overlapping of protection spheres
 - => Constant O₂ consumption and CO and CO₂ emission instantaneous rates

Conclusions and ongoing studies

- Conclusions
 - H₂ emission ↘ and oxygen consumption and CO₂ emission ↗
 - Oxidized defects created upon radio-oxidation act as energy sinks
 - Energy transfers towards radiation-induced defects are also effective under ion beam and under oxidative atmosphere

- Better understanding of aging mechanisms involved at very high doses, of primary importance for the deep underground repository

- Ongoing studies
 - Correlation between macromolecular defects and gas emission ?
 - => Better understanding of in-film modifications (FTIR, TGA, DSC...) in HDPE
 - Energy transfers evidenced in polyethylene: what about the other polymers?
