

# Clustering in bubble swarm with DNS and Front-Tracking method

April, 4 2023

Gabriel RAMIREZ<sup>1,2</sup>, Alan BURLOT<sup>1</sup>, Frédéric RISSO<sup>2</sup>,  
Guillaume BOIS<sup>1</sup>, Rémi ZAMANSKY<sup>2</sup>

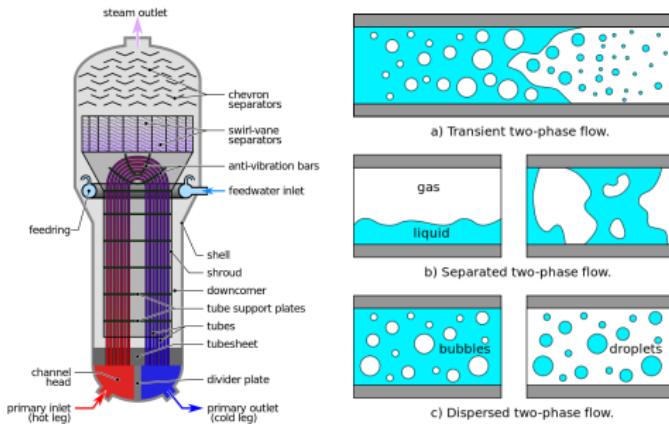

<sup>1</sup>CEA PARIS-SACLAY (FRENCH ATOMIC ENERGY COMISSION)

<sup>2</sup>INSTITUT DE MÉCANIQUE DES FLUIDES, TOULOUSE - CNRS/Toulouse INP

# Introduction

- General purpose: get a better understanding of **boiling flows**
- Development of **multiphase RANS modeling** for design and safety analysis
- Along experimental apparatus, use **DNS** to improve our understanding of physical mechanisms

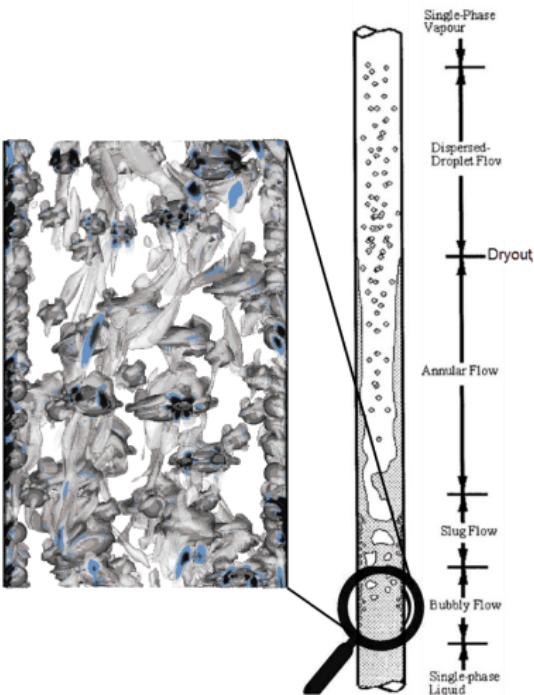

# Industrial purposes and boiling flows

## Boiling crisis

- Safety issue for press. water reactor
- Rode cladding integrity failure
- Decrease heat transfer at the wall: melting!

## Boiling flows

- Many different flow regimes
- Concern about the transition between bubbly and slug flows
- Bubbles at the wall → heat transfer increase
- Importance of the void fraction prediction
- A lack of understanding of dynamical phenomena (dispersion forces, turbulent dispersion, bubble-induced turbulence)

# Today's focus: clustering

- Why this concern?
- Numerous possible effects of clustering on modeling: local temperature, coalescence, momentum change and energy transfer mechanisms.
- Work of Bunner & Tryggvason (2002), Roghair *et al.* (2012)
- Many configurations to be considered (void fraction, viscosity effect, surface tension, etc.) **At high pressure, high void fraction flow stays bubbly.**
- Need to explore its behavior to correctly model the transition to more complex regimes (for instance Kuidjo *et al.* (2023))

**Can we identify clustering effect in our simulations? Is there an influence of turbulence?**

# TRUST/TrioCFD & FieldZ

- TRUST/TrioCFD : **Open-source C++ code for DNS, LES, RANS** modeling of single and two-phase flows
- **Interface capturing method** using a mixed VOF/**Front-Tracking** method
- RK3 time scheme
- One-fluid formulation

$$\begin{aligned} \frac{\partial \chi_k \rho_k \vec{u}_k}{\partial t} + \nabla \cdot (\chi_k \rho_k \vec{u}_k \otimes \vec{u}_k) = \nabla (\chi_k p_k) + \chi_k \rho_g \vec{g} \\ + \nabla \cdot \left( \chi_k \mu_k \left[ \nabla \vec{u}_k + \nabla^T \vec{u}_k \right] \right) - (p_k \vec{n}_k - \vec{\tau}_k \cdot \vec{n}_k) \cdot \nabla \chi_k \end{aligned}$$

with

- $\chi_k$  the phase indicator function (equals 1 in phase  $k$ , 0 otherwise)
- velocity continuity
- interfacial normal stress balance:  $\Sigma_k (p_k \vec{n}_k - \vec{\tau}_k \cdot \vec{n}_k) = -\sigma \kappa \vec{n}$
- FieldZ: R. ZAMANSKY's spectral code, used for *a posteriori* spectral analysis in G. RAMIREZ's PhD

# Turbulence forcing

- External random forcing proposed by Eswaran & Pope (1987)
- Used in two-phase flow by Chouippe & Uhlman (2015)
- **Two parameters**
  - $T_L$  the characteristic time scale of the random process
  - an effective dissipation  $\varepsilon^* = T_L \times \sigma$  with  $\sigma$  the random process variance
- Objective (G. RAMIREZ's PhD, not today's focus): how turbulence will affect the kinetic energy budget?
- Forcing on the 3 largest Fourier modes: **no direct coupling** with the bubble dynamics.

# Bubbles and the swarm

## Non-dimentional parameters

### Geometrical parameters

- Domain length:  $L$
- Bubble diameter:  $d_b$
- Cell size:  $\Delta_x$

- Mesh convergence:  $\frac{d_b}{\Delta_x} \geq 20$
- Non-overlapping:  $\frac{L}{d_b} \geq 30$
- Simulation cost:  $N^3 = (\frac{L}{\Delta_x})^3 \approx 600^3 \sim 10^8$

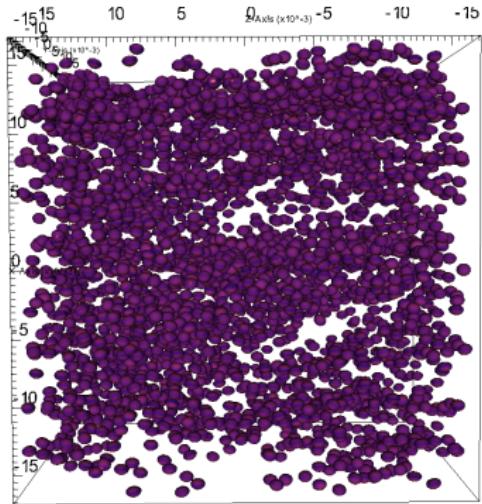

### Physical parameters

- Liquid phase:  $\rho_l; \mu_l$
- Vapor phase:  $\rho_v; \mu_v$
- Void fraction:  $\alpha$
- Surface tension:  $\sigma$
- Gravity:  $g$

- Ratio liquid vapor:  $\frac{\rho_l}{\rho_v} = 13; \frac{\mu_l}{\mu_v} = 1$
- Deformation:  $Bo = \frac{\Delta_p g d_b^2}{\sigma} = 0.6$
- Wake Instability:  $Ar = \frac{d_b \sqrt{\frac{\Delta_p}{\rho_l} g d_b}}{\nu} = 300$
- Void fraction:  $\alpha = 3\%; 6\% (N_b = 1825 \text{ and } N_b = 3650, \text{ resp.})$
- Bubble Reynolds number:  $Re_b = 319$

# Results

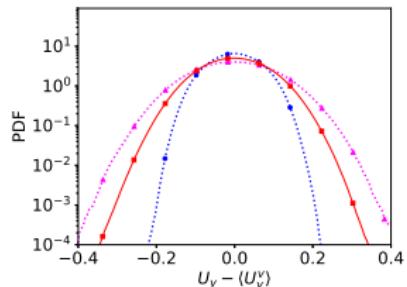

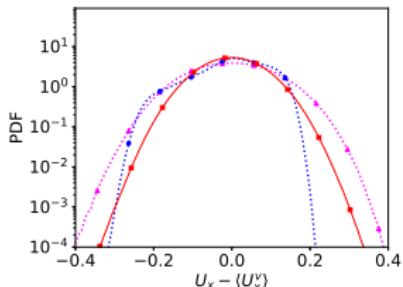

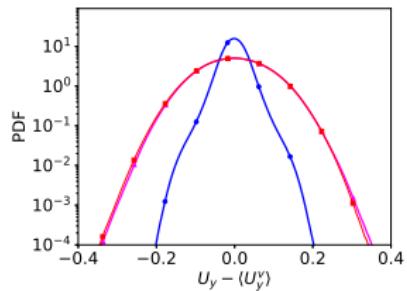

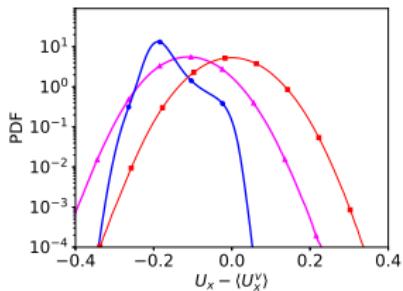

Swarm of 3650 bubbles ( $\alpha = 6\%$ )

- 1 **PDFs** of liquid and vapor horizontal and vertical velocities
- 2 **Kinetic energy spectra** of BIA, THI and the coupled THI-BIA computations
- 3 **PDFs of the Voronoï volumes** for a 3 % and 6 % computations (with a few words on modelling it)
- 4 **Radial distribution functions**, compared with a random distribution

# PDFs

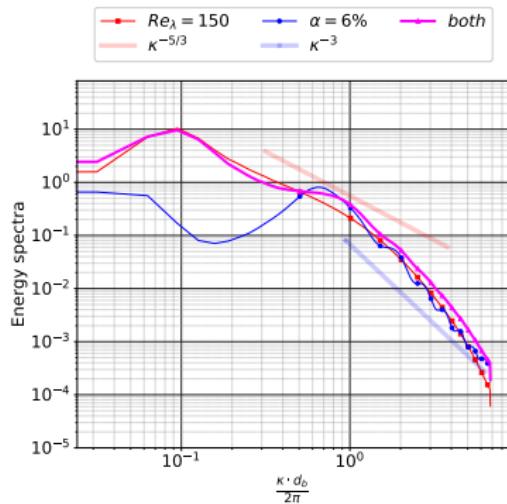

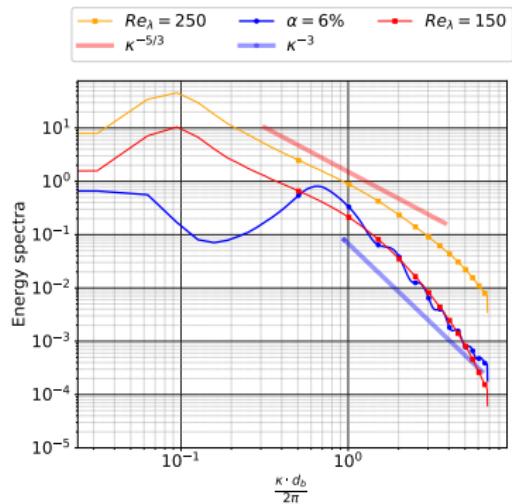

- **BIA** = bubbles-only, **THI** = single-phase forcing only, **THI+BIA** = coupled simulation of bubbles+forcing
- Top = liquid, bottom = vapor. Left = axial, right = transverse

# Spectra

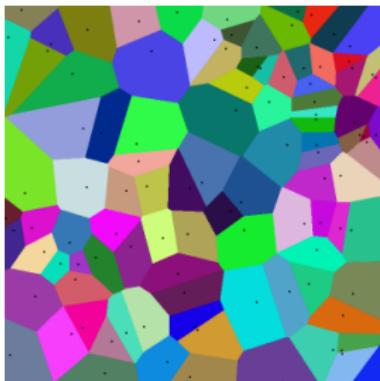

- Forcing adjusted not to wipe BIA energy
- Magenta curve: THI + BIA kinetic energy spectra

# Voronoi method

- Voronoï volumes equivalent to concentration field
- **Small volumes means high concentration**
- 3D tessellation using SciPy

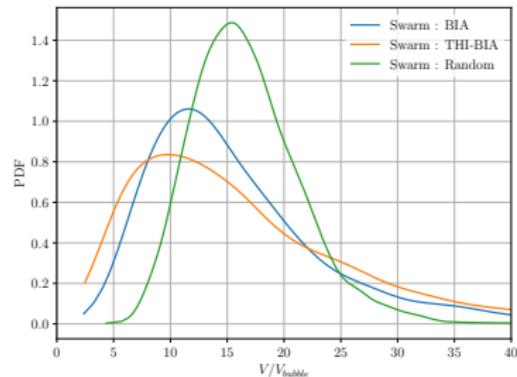

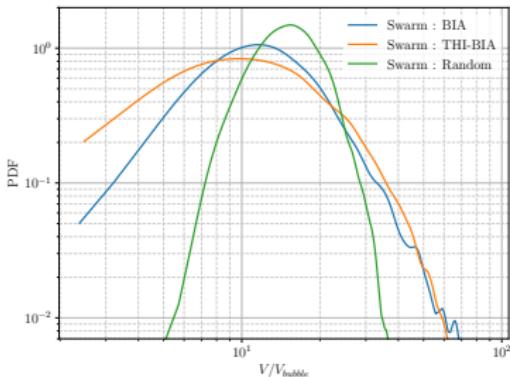

2D Voronoï tessellation, from Wikipedia

- R. MONCHAUX et al. "Analyzing Preferential Concentration and Clustering of Inertial Particles in Turbulence". *International Journal of Multiphase Flow* 40 (2012), p. 1-18
- Y. TAGAWA et al. "Three-Dimensional Lagrangian Voronoï Analysis for Clustering of Particles and Bubbles in Turbulence". *Journal of Fluid Mechanics* 693 (2012), p. 201-215
- Y. LIU et al. "Life and Death of Inertial Particle Clusters in Turbulence". *Journal of Fluid Mechanics* 902 (2020)

# Voronoi tesselation, $\alpha = 6\%$

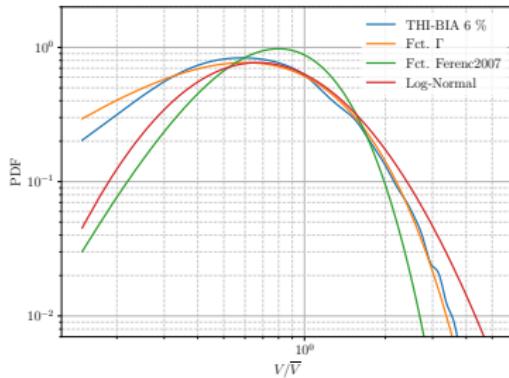

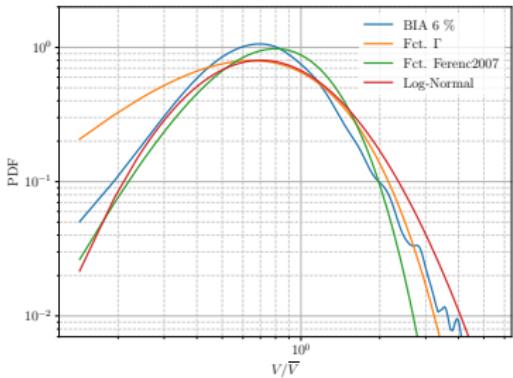

- Lots of work with particles or very small bubbles
- **Objective:** identify a parameter that characterizes the cluster
- Turbulence tends to spread the distribution: more small volumes
- Random = random distribution at startup with exclusion zone

# Voronoi tesselation, $\alpha = 6\%$

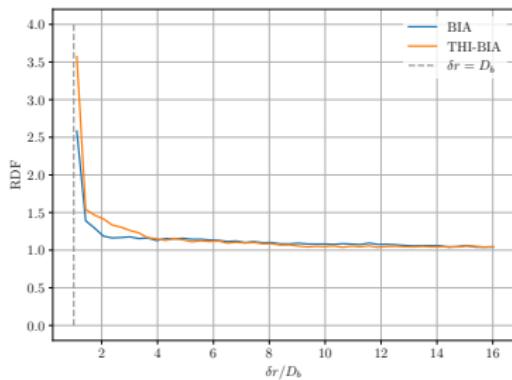

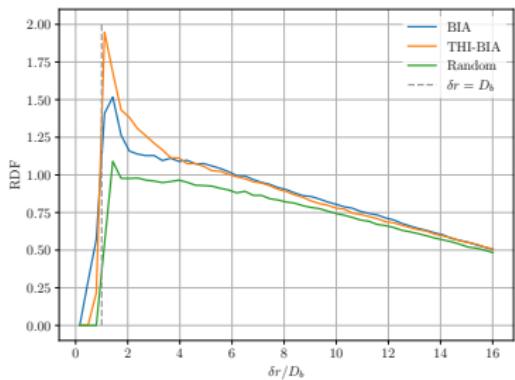

- Can we model the distribution?
- Literature suggests BIA is close to a log-normal distribution
- Literature suggests THI+BIA should be closer to a  $\Gamma$  function  $f(V, \text{std}(V))$
- Ferenc2007:  $f(V) = \frac{3125}{24} V^4 \exp(-5V)$

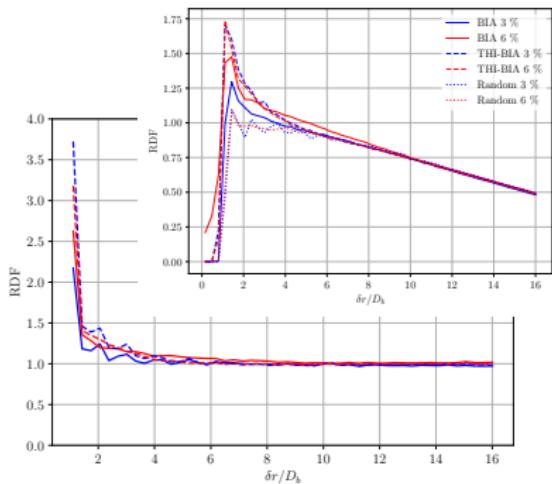

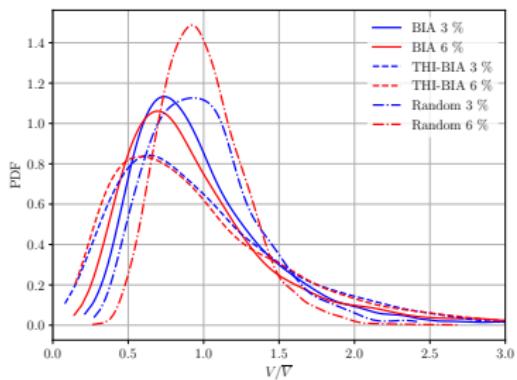

# Radial distribution function, $\alpha = 6\%$

- Right: divided by the random distribution
- In coherence with Voronoï measure, bubble concentration at small radius
- $\text{RDF} = 1$ , uniform concentration.  $\text{RDF} > 1$ , excess concentration

# Comparison between $\alpha = 3\%$ and $\alpha = 6\%$

- Voronoï pdfs, abscissa normalized by mean Voronoï volume to superimpose curves
- Turbulence removes differences between  $\alpha = 3\%$  and  $\alpha = 6\%$

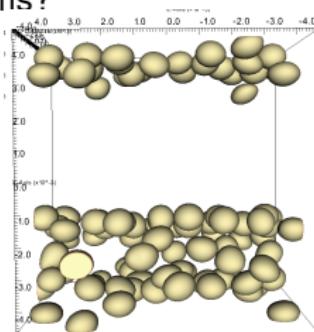

# Finale

## Conclusion

- Preliminary results!
- Effect of turbulence forcing on concentration:
  - larger vapor velocity fluctuations **and** higher probability of concentration
  - Same concentration on both  $\alpha = 3\%$  and  $\alpha = 6\%$
- Not shown: no horizontal packing as in Roghair or Brenner papers **for large swarm**, but packing for smaller swarms?

## Ongoing

- Plot angular distribution
- Larger void fractions?
- Small domain effect?
- Study bubbles trajectories

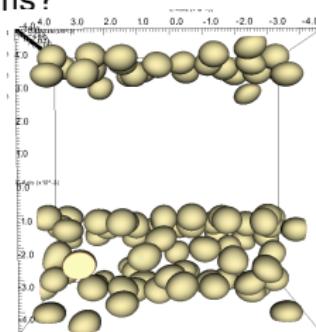

# Finale

## Conclusion

- Preliminary results!
- Effect of turbulence forcing on concentration:
  - larger vapor velocity fluctuations **and** higher probability of concentration
  - Same concentration on both  $\alpha = 3\%$  and  $\alpha = 6\%$
