In the framework of the emulation of CPU-time expensive numerical simulators with Gaussian process (GP) regression, we propose in this work a new algorithm for the estimation of GP covariance parameters, referred to as GP hyperparameters. The objective is twofold: to ensure a GP as predictive as possible w.r.t. to the output of interest, but also with reliable prediction intervals, i.e. representative of GP prediction error. To achieve this, we propose a new constrained multi-objective algorithm for the hyperparameter estimation. It jointly maximizes the likelihood of the observations as well as the empirical coverage function of GP prediction intervals, under the constraint of not degrading the GP predictivity. Cross validation techniques and advantageous update GP formulas are notably used. The benefit brought by the algorithm compared to standard algorithms is illustrated on a large benchmark of analytical functions (with dimensions from 1 to 20 input variables). Different designs of experiments and different covariance models are considered. An application on a real data test case modeling an aquatic ecosystem is also proposed: GP metamodeling within a log-kriging approach is used to predict the biomass of a species at a given time. The multi-objective algorithm performs better than standard algorithms and this particular metamodeling framework shows the crucial interest of well-estimated and reliable prediction variances in GP regression.

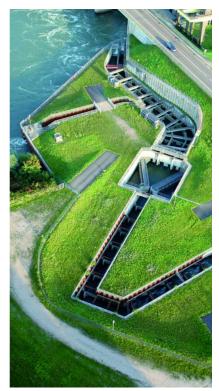

Gaussian process regression: new hyperparameter estimation algorithm for more reliable prediction

Application to an aquatic ecosystem model

Use of models and metamodels in UQ

edf

Use of models and metamodels in UQ

Reminders on GP metamodel

- ► Only a *n*-sample of simulations is available (Monte-Carlo, LHS, space-filling...) $D_{S} = \left(X_{S}^{(j)}, Y_{S}^{(j)}\right)_{1 \le i \le n} \text{ where } Y_{S}^{(j)} = \mathcal{M}\left(X_{S}^{(j)}\right)$
- Probabilistic surrogate model : response is considered as a realization of a random GP [RW06]:

 $Y(x) \sim GP(\mu(x), k(x', x))$ with $\mu(x)$ the mean and k(x', x) the covariance function.

 \Rightarrow The <u>predictive GP</u> is the GP conditioned by the observations (X_s , Y_s) :

$$Y(\boldsymbol{x}^*)|_{Y(X_s)=Y_s} \sim GP(\hat{\mu}(\boldsymbol{x}^*), \hat{s}(\boldsymbol{x}', \boldsymbol{x}^*))$$

With analytical formulations for $\hat{\mu}(x^*)$ and $\hat{s}(x', x^*)$

 \Rightarrow Conditional mean $\hat{\mu}(x^*)$ serves as the predictor

at location x^*

eDF

⇒ Prediction variance (*i.e.* mean squared error) is given by conditional covariance $\hat{s}(x^*, x^*)$

⇒ Prediction interval of any level α can be built at any location x^*

Reminders on GP metamodel

In practice: parametric choices for trend function μ and covariance function k

 $Y(\boldsymbol{x}) \sim GP(\mu(\boldsymbol{x}), k(\boldsymbol{x}', \boldsymbol{x}))$

 \Rightarrow For μ : either constant or linear basis

 \Rightarrow For k: tensorized 1-D covariance functions of v-Matérn (with $h = |x - \tilde{x}|$)

$$k_{\sigma,\nu,\theta}(x,\tilde{x}) = \sigma^2 \frac{2^{1-\nu}}{\Gamma(\nu)} \left(\frac{\sqrt{2\nu}h}{\theta}\right)^{\nu} K_{\nu}\left(\frac{\sqrt{2\nu}h}{\theta}\right)$$

 \Rightarrow Need to estimate from the dataset the correlation hyperparameters $\theta \in \mathbb{R}^{+,d}$

How to ensure that the estimated hyperparameters θ yield good predictivity but also reliable GP prediction intervals?

⇒ Crucial for safety applications: a « reliable » confidence interval is required on an estimated quantity of interest related to safety (as a high-order quantile)

See application in nuclear safety in [IL19,ILG19]

Especially in large dimension (d > 10) and small dataset ($n \approx 100$)

edf

GP estimation and validation

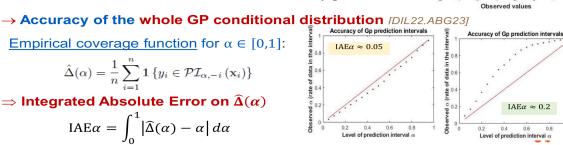

► Usual estimation methods [KO23,Mur21,Pet22]

- → Maximum likelihood-based estimation (MLE) ⇔ minimization of NLL
- \rightarrow Cross-validation-based estimation: minimization of RMSE= $\left\{\frac{1}{n}\sum_{i=1}^{n}(y_i \hat{y}_i)^2\right\}$
- → Bayesian approaches (CPU ++)

► Validation criteria computed by cross-validation (LOO)

- \rightarrow Accuracy of the GP predictor: $Q^2 = 1 \text{RMSE}^2/\text{Var}(Y)$
- → Accuracy of the predictive variance: PVA =

e:
VA =
$$\left| \log \frac{1}{n} \sum_{i=1}^{n} \frac{(y_i - \hat{y}_i)^2}{\hat{s}_{-i}^2} \right|$$

We note $y_i = y(x_i)$ $\hat{y}_i = \hat{\mu}(x_i)$

Predictivity

 $Q^2 \approx 0.90$

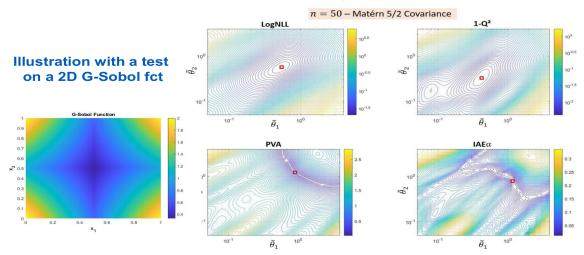

Study of criteria NLL, Q^2 , PVA and $IAE\alpha$ on many test cases

→ Close behavior of NLL and $Q^2 \Rightarrow$ keep NLL as the main estimation objective to ensure the predictivity of the metamodel \Rightarrow Consistent with [PBF+23,Pet22]

\rightarrow Similar behavior of PVA and IAE α but more irregular w.r.t. θ

 \Rightarrow Some local minima compatible with optimal values of the other criteria \Rightarrow No to be optimized independently of the others

New estimation algorithm for GP hyperparameters

From these understandings:

 \rightarrow Close behavior of NLL and $Q^2 \Rightarrow$ keep NLL as the main estimation objective to ensure the predictivity of the metamodel

 \rightarrow IAE α more directly related to reliable predictive intervals, than PVA

→ In the neighborhood of the optimal NLL point, existence of better points θ w.r.t IAE α , but need to control the possible degradation of Q^2 value, which guarantees the predictivity

We propose the following algorithm:

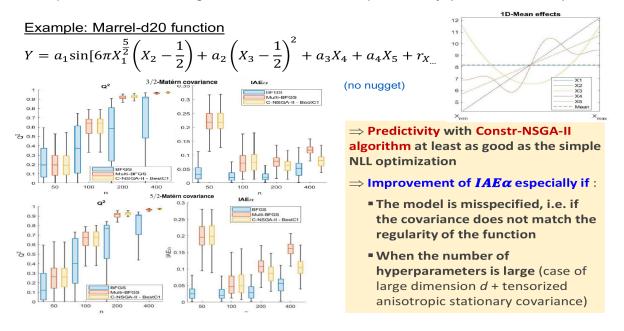

⇒ Optimization based on NLL and $IAE\alpha$ + Control of Q^2 ($IAE\alpha$ and Q^2 estimated by cross validation) ⇒ Proposition of a multi-objective NSGA-II algorithm with constraint on Q^2

edf

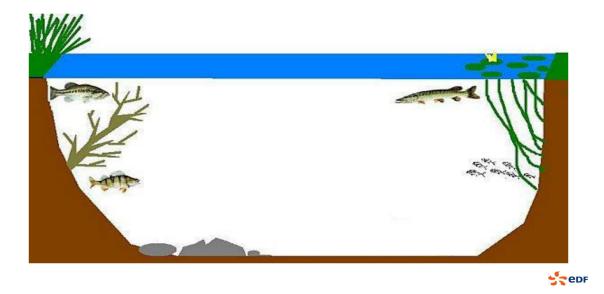

Intensive benchmark on test functions

d = 2 to 20, \neq covariance, \neq sample sizes, \neq DoE, with/without nugget effect Comparison with usual algorithms based on NLL optimiz. only (BFGS/multistart)

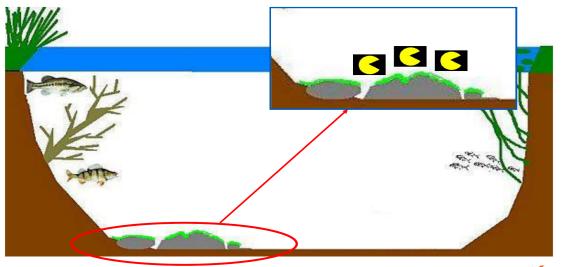

Application: aquatic prey-predator chain model

Studies of biological contamination of rivers

Application: aquatic prey-predator chain model

EDO-type equations describing the growth of microorganisms, periphyton, grazing and prey-predator interactions

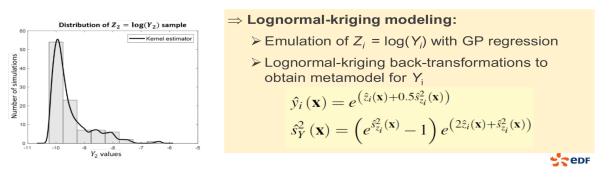

Application to an aquatic ecosystem model

- MELODY model: prey-predator chain in an aquatic ecosystem
- [IPB+12]

- d = 20 uncertain inputs:
 - Periphyton: photosynthesis/mortality/excretion rates, survival temperature, saturation constants, ...
- Grazers: consumption/assimilation/mortality/excretion rates, survival temperature, ...
- 2 outputs of interest: Periphyton (Y₁) and Grazers (Y₂) biomasses at day n°60
- Sample of *n* = 100 simulations of the model MELODY (space-filling design)

Need of preliminar logarithmic transformation

Results

Additional comparison with Bayesian RobustGaSP approach [GWB18]

\Rightarrow With nugget effect (included in the set of GP hyperparam	eters to be estimated)
--	------------------------

Data	Covariance	Predictivity Coefficient Q ²		ΙΑΕα			
		Multi-BFGS	C-NSGA-II-BestC1	RobustGaSP	Multi BFGS	C-NSGA-II-BestC1	RobustGaSP
Y ₂	Matern3/2	0,70	0,74	0,25	0,10	0,07	0,04
	Matern5/2	0,77	0,82	0,66	0,09	0,02	0,07
	Gaussian	0,75	0,79	0,66	0,08	0,02	0,06

 \Rightarrow Best results with Constr-NSGA-II algorithm: better Q^2 and IAElpha

⇒ Without nugget effect

Data	Covariance	Predictivity Coefficient Q ²		ΙΑΕα			
		Multi-BFGS	C-NSGA-II-BestC1	RobustGaSP	Multi BFGS	C-NSGA-II-BestC1	RobustGaSP
	Matern3/2	0,70	0,75	0,47	0,10	0,06	0,03
Y ₂	Matern5/2	0,78	0,84	0,83	0,08	0,02	0,07
	Gaussian	0,70	0,72	0,89	0,06	0,03	0,06

 \Rightarrow Better behavior of RobustGasp <u>without</u> nugget : best Q^2 but not IAElpha

 \Rightarrow Constr-NSGA-II algorithm is also more robust to modeling choices

~edf

Conclusions & Perspectives

- High benefits of considering validation criteria of the whole GP distribution when estimating hyperparameters ⇒ enables more robust estimation !
- Particular attention must be paid to GP validation
- Part of a more general effort to ensure confidence in machine learning models
- Perspectives: some are methodological but the main ones concern software & industrial deployment of GP!
