HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Temperature Dependence of 1200V-10A SiC Power Diodes: Impact of Design and Substrate on Electrical Performance

Introduction: Bulk 4H-SiC substrates growth requires a long, energy-intensive and costly process, which limits the availability of SiC substrates for devices production today. Consequently, 3C-poly silicon carbide substrates (pSiC) are currently being considered as an alternative for SiC power devices fabrication. For example, utilizing the Smart Cut™ technology, SmartSiC™ substrates are engineered to achieve better device yield and to optimize conduction losses [1] by bonding a high quality mono crystalline 4H-SiC layer on top of a low resistivity poly-SiC substrate (reported to offer about one order of magnitude lower resistivity values [1]). In this work, we study the impact of temperature on the static electrical parameters of 1200V power 4H-SiC diodes with various designs and architectures (Schottky, JBS, hexagonal and stripe cells) fabricated on 150 mm bulk 4H-SiC and 3C-pSiC based substrates (SmartSiC™). Additionally, switching characteristics were investigated, revealing no significant dependency on the substrate type.

Devices Fabrication: Three power diodes architectures (Schottky, PiN, and JBS: **Fig. 1a-b**) were fabricated with a process flow designed for 1200V blocking voltage capability [2], with Al implanted p+ guard rings and a JTE annealed at 1700°C to achieve the breakdown voltage target (**Fig. 1c**). Various anode and edge terminations were designed and fabricated on both 4H-SiC bulk and SmartSiC™ substrates (**Fig. 1d**). The substrates were not thinned and backside contact formation was performed using laser annealing.

Results and Discussion: I(V) measurements were carried out in both reverse and forward modes to assess the impact of designs and substrates. **Fig. 2** highlights the off-state characteristics with examples of three reference diode types that were reverse biased on both bulk and SmartSiC™. Non-destructive avalanche mode was reached with similar performance (leakage, V_{AV}) observed for both substrates (due to identical drift layer and device structure). Wafers mapping and yield evaluation confirmed a minimal substrate contribution to defects that could propagate to the epilayer, leading to off-state performance degradation such as BPDs or TEDs [3]. As expected from SiC impact ionization coefficients, avalanche voltage increased at elevated temperatures for all designs and substrates types.

Specific differential resistance (R_{DIF}) decreased as Schottky surface ratio increased for both bulk and pSiC-based substrates (**Fig. 3**). With our design, hexagonal configuration resulted in lower resistances (**Fig. 3b**). In all cases, the JBS fabricated on SmartSiC™ exhibited a high current conduction and less resistance in the ohmic regime (Fig. 3a), confirming the impact of the substrate resistivity. **Fig. 4** shows the JBS R_{ON-BV} figure of merit for the studied samples with a comparison to state-of-the-art JBS diodes [4]. The observed conduction gain for the SmartSiC™ sample (compared to bulk) was further investigated at high temperatures in **Fig. 5**. This figure illustrates that the extracted R_{DIF} between 25 to 200°C exhibited an exponential temperature dependence. At 200°C, the absolute R_{DIF} difference further increased by +0.5 mΩ.cm² with a relative difference remaining at 21%. **Fig. 6** proposes another way to evaluate the impact of the diode design/substrate on the resistance-temperature dependence by plotting $R_{DIF}(200^\circ\text{C})$ versus $R_{DIF}(25^\circ\text{C})$. Based on the observed trend across all data (including additional 1.7 kV epiwafer with same device process [2] and ref [5]) we can infer that all diodes designs (regardless of the epi or the substrate) follow the same predictive $R_{DIF}(T)$ model proposed in Fig. 6. In **Fig. 7**, Schottky R_{DIF} at 200°C has been segmented into its three main contributions. SmartSiC™ substrate (350μm, no thinning) exhibits lower resistance even compared to thinned (110μm) bulk epiwafer.
